

ACQUIRED APHASIA VS. PRIMARY PROGRESSIVE APHASIA

While we are excited to see Aphasia in the news, recently, news sources have been using “Aphasia” to describe both **Acquired Aphasia** and **Primary Progressive Aphasia**. Which unfortunately, can spread incorrect information. We want to provide information and resources on both Acquired Aphasia and Primary Progressive Aphasia.

Acquired Aphasia (Aphasia): Often just referred to as “Aphasia”, is usually the result of a stroke or traumatic brain injury in the left hemisphere. Aphasia is a LANGUAGE disorder. It results in difficulty accessing language, causing impairments in verbal expression, language processing, reading, and writing. Difficulties with word retrieval (including numbers) is a hallmark of Aphasia, and sentence formulation is often quite challenging.

Key points to remember:

- There is no cure for acquired Aphasia, but research has shown that patients can always continue to improve with therapy.
- Acquired Aphasia does not impact your intelligence and patients DO NOT decline over time.

Primary Progressive Aphasia (PPA): Primary Progressive Aphasia, also known as PPA, is a degenerative neurological condition in which language capabilities become impaired over time.

Key points to remember:

- It is different from other forms of Aphasia, as there must be no focal lesion for a diagnosis of PPA to occur.
- PPA results in deterioration of brain tissue important for speech and language and patients CAN decline over time.
- PPA is NOT the same as Alzheimer’s Disease, it is a subtype of Frontotemporal Dementia (FTD)

Below are additional resources you can explore to learn more about Aphasia, Primary Progressive Aphasia and the differences between them.
